Quantum key exchange can be broken in 5 hours.

Major providers are testing quantum-safe HTTPS, which shrinks certificates by 90%. Latency decreases.

This likely involves a mix of TLS 1.3's 0-RTT resumption and certificate compression. TLS 1.3 doesn't provide full protection against quantum attacks, though.

Are your security frameworks prepared for a post-quantum world? Should you be worried about the first quantum-enabled ransomware attack?

Would you use Zeek to detect anomalies or Suricata?
