

****Kernel Panic**** ****Bad Epoll**** hits Linux. It's a kernel flaw. CVE-2026-46242 lets users take control as root. Affects Linux desktops, servers, and Android. Fix available. But will systems patch in time?

Our team saw this last week. Unpatched
Linux server. Compromised due to a known
vulnerability. Sophisticated attack. Novel
obfuscation technique. Variant of the
CVE-2026-46242 exploit.

Identity-centric security is key. Verify and validate users and devices. But one misconfigured system can bring down the network. ****Bad Epoll**** is a reminder. ****100% visibility**** is necessary. Not a luxury. Would you rather have ****100% visibility**** with ****5% false positives****, or ****60% visibility**** with ****0%****? No. ****Most organizations will be breached within 6 months if they don't patch this vulnerability.**** ---
