

\$ **LOGS DIDN'T MATCH.**

****Logs didn't match.**** 12 minutes to exfiltration. What's the cost of a missed patch?

\$ **LOGS DIDN'T MATCH.**

Patch management is key. It's not straightforward. Many teams struggle to prioritize patches. Our team learned this the hard way: 72 hours to detect and 48 hours to respond, but if we had patched sooner, no breach would have occurred. They used a novel **obfuscation technique** that evaded our **SIEM**.

The FCC's softened ban on foreign-made routers increases the attack surface, with ****74% of organizations**** having been breached due to network vulnerabilities. No visibility, or 60% visibility with no false positives, is a choice we must make. As a practitioner, I recall a recent incident where automated patch management saved us from a major breach, and another where vulnerability scanning revealed a critical flaw that had gone undetected for months.
