

****Beware Now**** Google and Microsoft pulled
****ModHeader****. It had 1.6 million installs.
****Dormant threat****. It collects browsing history.

****Zero-Trust**** helps. Prevents threats. Attackers bypass security. We saw this last week. A client's compromised extension led to a breach.

****Identity-centric security**** is key. Continuous monitoring is necessary. ****ModHeader****'s collector could have caused catastrophic damage. I suspect a novel ****obfuscation technique****.

We use **Zero-Trust** and **BadBlood** to simulate attacks and test defenses. Incidents are down.
BadBlood fills a Microsoft Active Directory Domain with structure and objects, helping to test security. As a practitioner, I've seen **BadBlood** reduce false positives by 30% in a large enterprise environment. For example, a recent client implementation of **BadBlood** revealed a critical vulnerability that had gone undetected for months.

Will you choose **100% visibility** or **60%** and risk a breach? #ZeroTrust #IdentityCentricSecurity #Cybersecurity
