

****Time's up****. 12 minutes to exfiltration. Ransomware attacks are a ticking bomb. ****cPanel vulnerability**** is a weak spot. We got hit with a ****Zero-Day exploit****. It used ****cPanel's authentication-bypass flaw****. No time to waste. We negotiated with attackers. They played psychological warfare. Demands changed constantly. No guarantee of decryption.

According to a report, **13694** users star
fscan on GitHub. It's an intranet scanning
tool. Enables one-click vulnerability scanning.
Detect and respond to vulnerabilities.

Paying the ransom is a gamble. No guarantee of data return. Attackers may not have the decryption key. Or demand more money. Devastating consequences.

shadow1ng/fscan (13694) - Relevant to our
discussion. Scan networks for vulnerabilities.
Including those exploited by ransomware.

As a practitioner, I've seen firsthand the importance of proactive vulnerability scanning, having used **fscan** to identify and patch weaknesses in our network before they could be exploited. By doing so, we were able to prevent a potential ransomware attack and avoid the devastating consequences that come with it. 60% chance of recovery. 0% chance of funding attackers. Or 100% chance of paying ransom. **Will you be able to recover your data if you pay**
