

****Zero-Day Alert**** Metabase exploited. CVSS score: 10.0. No CVE identifier. ****High risk****. Attackers gain admin access without authentication.

Most teams fail to assume their security controls are inadequate, and zero-day exploits bypass defenses. Our team saw this last week, but layered security and monitoring helped.

****Vulnerability assessment**** is key, and ****penetration testing**** (VAPT) identifies flaws, allowing for remediation before exploitation. The CVSS score of 10.0 poses significant risk, and the lack of a CVE identifier makes it harder to prioritize.

As a practitioner, I recall a recent incident where VAPT helped identify a critical flaw, which was then remediated before it could be exploited. This experience highlights the importance of regular vulnerability assessments in preventing attacks.

It's bad, and the question is: **can your organization afford to be the next target?** #ZeroTrust #VAPT #Cybersecurity
