

****Ransomware Wins**** GodDamn ransomware uses PoisonX. It neutralizes security software. Symantec's Threat Hunter Team reports this. First instances emerged last week. PoisonX driver disables endpoint defenses. This increases successful ransomware attacks by 30%.

Our team responded to a ransomware incident where the attacker used a similar technique, taking us hours to contain the threat. We should have monitored endpoint logs to detect kernel driver manipulation earlier. Average time to detect ransomware: 3 days, but some cases take 6 months to discover. Have a plan to detect and respond to such threats. Patch it or get breached. Monitor endpoint logs now.

As a practitioner, I've seen firsthand how crucial it is to stay vigilant, and in one instance, our team's prompt response to a ransomware alert saved a client from a potential breach. By leveraging tools like toby-bridges/api-relay-audit, which detects prompt injection and model substitution, we can proactively identify AI-powered system vulnerabilities. ---

****Tool Recommendation**:** toby-bridges/api-relay-audit (752) detects prompt injection. It detects model

substitution and security threats. I use it to identify
