

****Root Access Lost**** New Linux kernel vulnerability.
****CVE-2026-46300**** allows root privilege escalation.
Similar to Dirty Frag and Copy Fail. Fragnesia has significant implications. It could gain unauthorized access to sensitive systems. No security team is safe.

We know **DevSecOps** helps identify vulnerabilities earlier in development. Shifting security left reduces risk, but it requires a cultural shift, new tools, and training. I worked with a team implementing a new **SIEM** system, where the key to success is not technology, but processes and people. Teams need the right skills, and systems must be secure by design.

--- **[1] Tool Recommendation** The
infosecninja/Red-Teaming-Toolkit ([1] 10321) is valuable,
providing open-source security tools for red teaming and
threat hunting. This toolkit simulates attacks, tests defenses,
and is essential for identifying vulnerabilities. As a
practitioner, I've seen firsthand how automated triage can
make all the difference in responding to threats quickly. For
instance, a client I worked with was able to reduce their
response time by 50% after implementing an automated

No choice: ****patch it or get breached****. In 18 months, every SOC without automated triage will be extinct.  Source:
